Comparison of VACUETTE® K₂EDTA and VACUETTE® K₃EDTA Tubes

**Background:**
The VACUETTE® evacuated blood collection tubes are used for testing parameters in haematology. The tubes are available with interior coated spray-dried K₂EDTA (dipotassium ethylenediaminetetraacetic acid) or K₃EDTA (tripotassium ethylenediaminetetraacetic acid).

Both EDTA salts inhibit the coagulation of the blood specimen by binding Calcium (Ca²⁺), thus preserving the blood cells for test analyses.¹

The K₃EDTA and K₂EDTA additives preserve erythrocytes, leucocytes and thrombocytes up to 24 hours. The differential should be analyzed and the peripheral smear be made within 3 hours of specimen collection.²

**Study Objective:**
A clinical evaluation was carried out to compare the performance of the VACUETTE® K₂EDTA tube to the VACUETTE® K₃EDTA tube.

**Study design:**
The following tube types were used in this study:

<table>
<thead>
<tr>
<th>Sample ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>VACUETTE® K₂EDTA 4 ml, spray dried (item No.: 454023)</td>
</tr>
<tr>
<td>B</td>
<td>VACUETTE® K₃EDTA 4 ml, spray dried (item No.: 454021)</td>
</tr>
</tbody>
</table>

Blood was collected from forty-six normal and abnormal donors. The instructions for use² was followed. The order of draw was also randomized.

All salts of EDTA are hyperosmolar, which causes water to leave the cells and results in cell shrinkage. The higher the concentration of EDTA, the greater the osmotic withdrawal of water from the cells. It was therefore ensured that the tubes are filled completely.

In addition, under-filling of the tubes also decreases the blood to additive ratio, resulting in cell shrinkage (reduction of the Mean Corpuscular Volume and an increase of the Mean Corpuscular Haemoglobin Concentration³). The K₂EDTA Tubes may be slightly more affected, because of the presence of the higher potassium-ion concentration.

Blood specimens were obtained using the institution’s standard phlebotomy techniques. Immediately following blood collection, the tubes were gently inverted 8 to 10 times to ensure proper mixing of the blood and additive in the specimens.

Determination of the most common parameters (listed below) in hematology was performed using the Sysmex XE2100 Hematology Analyzer with accompanying reagents.

Specimens were analyzed as follows:
1) Seven donors were analyzed within 15 minutes after blood collection.
2) Fifteen donors were analyzed between 15-30 minutes after blood collection.
3) Twenty-four donors were analyzed between 30 minutes and 3 hours after blood collection.
4) All samples were reanalyzed 24 hours after blood collection.

The tubes were stored at room temperature.

The results were checked for correctness. If an outlier was observed, an investigation was conducted and the test was repeated.

The evaluation of the results included directly measured and calculated parameters.

Directly measured parameters included Leukocytes, Erythrocytes, Haemoglobin, Hematocrit and Thrombocytes.

The calculated parameters included Mean Corpuscular Volume (MCV), Mean Corpuscular Haemoglobin (MCH) and Mean Corpuscular Haemoglobin Concentration (MCHC).

The differential parameters included Neutrophil Granulocytes, Lymphocytes, Monocytes, Eosinophile Granulocytes and Basophile Granulocytes.

**Conclusion:**
The VACUETTE® K₂EDTA tube demonstrated substantially equivalent performance to the VACUETTE® K₃EDTA tube. No clinically significant differences were observed.
